Quiz 4

Quiz, 6 questions

6/6 points (100%)

Congratulations! You passed!

Next Item

1. Consider the space shuttle data ?shuttle
in the MASS
library. Consider modeling the use of the autolander as the outcome (variable name use
). Fit a logistic regression model with autolander (variable auto) use (labeled as "auto" 1) versus not (0) as predicted by wind sign (variable wind). Give the estimated odds ratio for autolander use comparing head winds, labeled as "head" in the variable headwind (numerator) to tail winds (denominator).

1 / 1 points

- -0.031
- 0.969 (selected)

Correct

```r
library(MASS)
data(shuttle)
## Make our own variables just for illustration
shuttle$auto <- 1 * (shuttle$use == "auto")
shuttle$headwind <- 1 * (shuttle$wind == "head")
fit <- glm(auto ~ headwind, data = shuttle, family = binomial)
exp(coef(fit))
```

```
## (Intercept)    headwind
##      1.3273      0.9687
```

```r
## Another way without redifing variables
fit <- glm(relevel(use, "noauto") ~ relevel(wind, "tail"), data =
    shuttle, family = binomial)
exp(coef(fit))
```

```
##                (Intercept) relevel(wind, "tail")head
##                     1.3273                    0.9687
```

- 1.327
- 0.031

2. Consider the previous problem. Give the estimated odds ratio for autolander use comparing head winds (numerator) to tail winds (denominator) adjusting for wind strength from the variable magn.

1 / 1 points

- 0.684
- 0.969 (selected)

Correct

The estimate doesn't change with the inclusion of wind strength

```r
shuttle$auto <- 1 * (shuttle$use == "auto")
shuttle$headwind <- 1 * (shuttle$wind == "head")
fit <- glm(auto ~ headwind + magn, data = shuttle, family = binomial)
exp(coef(fit))
```

```
## (Intercept)    headwind  magnMedium     magnOut  magnStrong
##      1.4852      0.9685      1.0000      0.6842      0.9376
```

```r
## Another way without redifing variables
fit <- glm(relevel(use, "noauto") ~ relevel(wind, "tail") + magn, data =
    shuttle,
    family = binomial)
exp(coef(fit))
```

```
##                (Intercept) relevel(wind, "tail")head
##                     1.4852                    0.9685
##                 magnMedium                   magnOut
##                     1.0000                    0.6842
##                 magnStrong
##                     0.9376
```

- 1.00
- 1.485

3. If you fit a logistic regression model to a binary variable, for example use of the autolander, then fit a logistic regression model for one minus the outcome (not using the autolander) what happens to the coefficients?

1 / 1 points

- The coefficients change in a non-linear fashion.
- The coefficients get inverted (one over their previous value).
- The intercept changes sign, but the other coefficients don't.
- The coefficients reverse their signs. (selected)

Correct

Remember that the coefficients are on the log scale. So changing the sign changes the numerator and denominator for the exponent.

4. Consider the insect spray data InsectSprays
. Fit a Poisson model using spray as a factor level. Report the estimated relative rate comapring spray A (numerator) to spray B (denominator).

1 / 1 points

- 0.136
- -0.056
- 0.9457 (selected)

Correct

```r
fit <- glm(count ~ relevel(spray, "B"), data = InsectSprays, family =
    poisson)
exp(coef(fit))[2]
```

```
## relevel(spray, "B")A
##               0.9457
```

- 0.321

5. Consider a Poisson glm with an offset, t
[Math Processing Error]. So, for example, a model of the form
glm(count ~ x + offset(t), family = poisson)
where x
is a factor variable comparing a treatment (1) to a control (0) and t
is the natural log of a monitoring time. What is impact of the coefficient for x
if we fit the model glm(count ~ x + offset(t2), family = poisson)
where 2 <- log(10) + t
? In other words, what happens to the coefficients if we change the units of the offset variable. (Note, adding log(10) on the log scale is multiplying by 10 on the original scale.)

1 / 1 points

- The coefficient estimate is divided by 10.
- The coefficient estimate is multiplied by 10.
- The coefficient is subtracted by log(10).
- The coefficient estimate is unchanged (selected)

Correct

Note, the coefficients are unchanged, except the intercept, which is shifted by log(10). Recall that, except the intercept, all of the coefficients are interpretted as log relative rates when holding the other variables or offset constant. Thus, a unit change in the offset would cancel out. This is not true of the intercept, which is interperted as the log rate (not relative rate) with all of the covariates set to 0.

6. Consider the data

1 / 1 points

```r
x <- -5:5
y <- c(5.12, 3.93, 2.67, 1.87, 0.52, 0.08, 0.93, 2.05, 2.54, 3.87, 4.97)
```

Using a knot point at 0, fit a linear model that looks like a hockey stick with two lines meeting at x=0. Include an intercept term, x and the knot point term. What is the estimated slope of the line after 0?

- 1.013 (selected)

Correct

```r
z <- (x > 0) * x
fit <- lm(y ~ x + z)
sum(coef(fit)[2:3])
```

```
## [1] 1.013
```
